

Organized Multi-scale Precipitating Convection and the Global Circulation

Mitchell W. Moncrieff
NCAR, USA

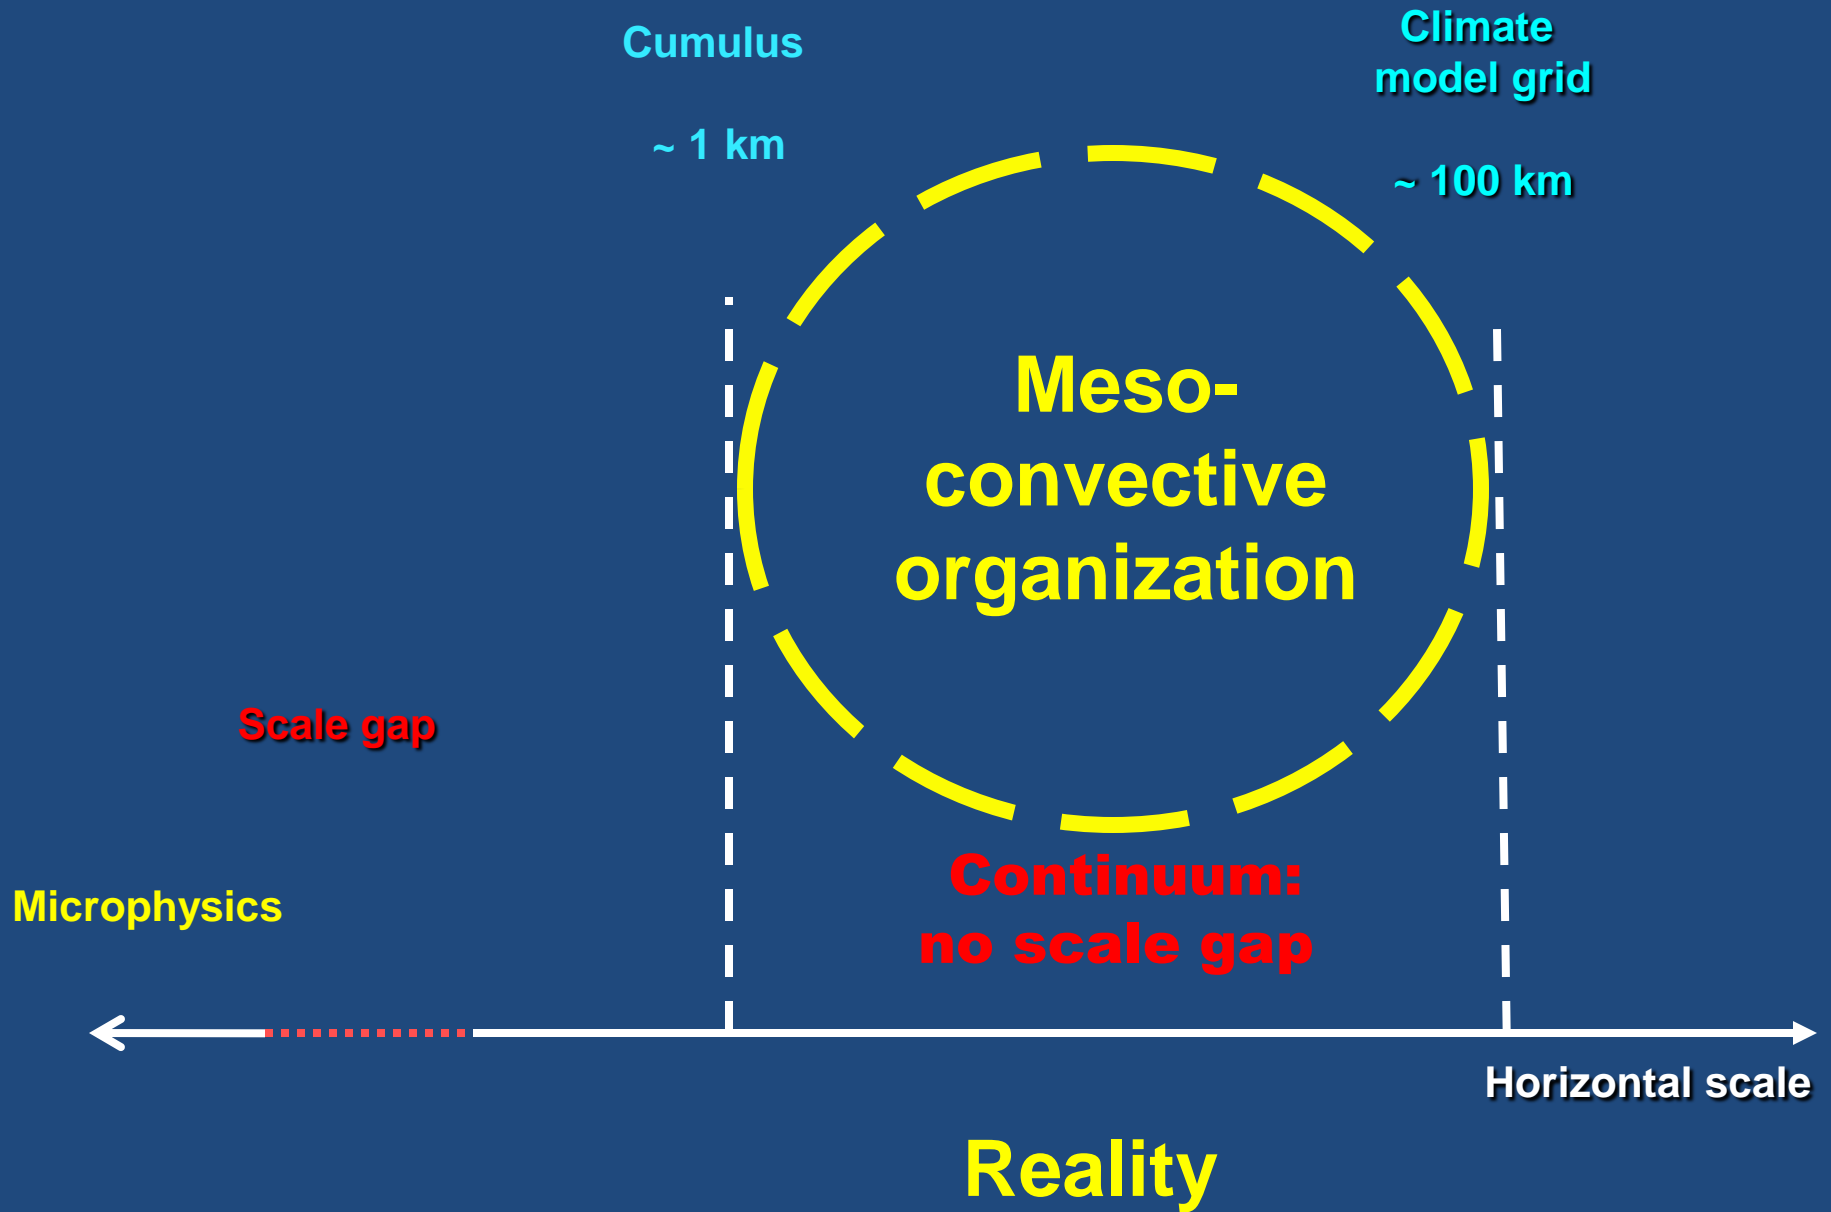

Workshop on High-resolution Climate Modeling, International
Centre for Theoretical Physics, Trieste, Italy, August 10-14, 2009

Organized convection and global models

- The amount and distribution of precipitation is strongly affected by convective organization
- We know much about convective organization as a process, much less about its large-scale effects and, especially, how it is represented in global models
- This state-of-affairs is changing in accord with models with resolution high enough to explicitly represent the mesoscale circulations associated with

Traditional parameterization

Three forms of energy

Parameterizations do not represent mesoscale circulations (red and blue trajectories)

The 3 energies (available potential energy; kinetic energy involving shear, work done by the pressure gradient) **define 2 key quantities:**

$$E = \frac{\Delta p}{\rho \frac{1}{2} (U_0 - c)^2}$$

$$R = \frac{CAPE}{\frac{1}{2} (U_0 - c)^2}$$

Traditionally:

Moist convection in global models represented solely by cumulus parameterization

Nowadays, explicit approaches:

- **Cloud-system resolving models (CRM; ~ 1 km grid) with computational domains up to global simulate meso-convective organization**
- **Large Eddy Simulation (LES; 100 m grids) resolves cumulus in domains ~ 200 km x 200 km**
- **Global NWP models; grid-scale circulations (under-resolved organization) occur along with cumulus parameterization**
- **Super-parameterization: 2-D organization represented by CRMs**

Cumulus parameterization remains an issue for climate models

Representing convective cloud systems of scale L in numerical models with grid-length Δ

a) Traditional parameterization

$$\Delta \ll L$$

b) Hybrid parameterization

$$\Delta \sim L$$

c) Explicit
(CRM & LES)

Upscale effects of organized convection and the MJO

Can MJO evolve by virtue of an “upscale cascade” of energy and momentum?

MCS-like & supercluster-like organization in a 2-D global-scale CRM

Grabowski and Moncrieff (2001)

MJO-like & supercluster-like organization in a superparameterized global model

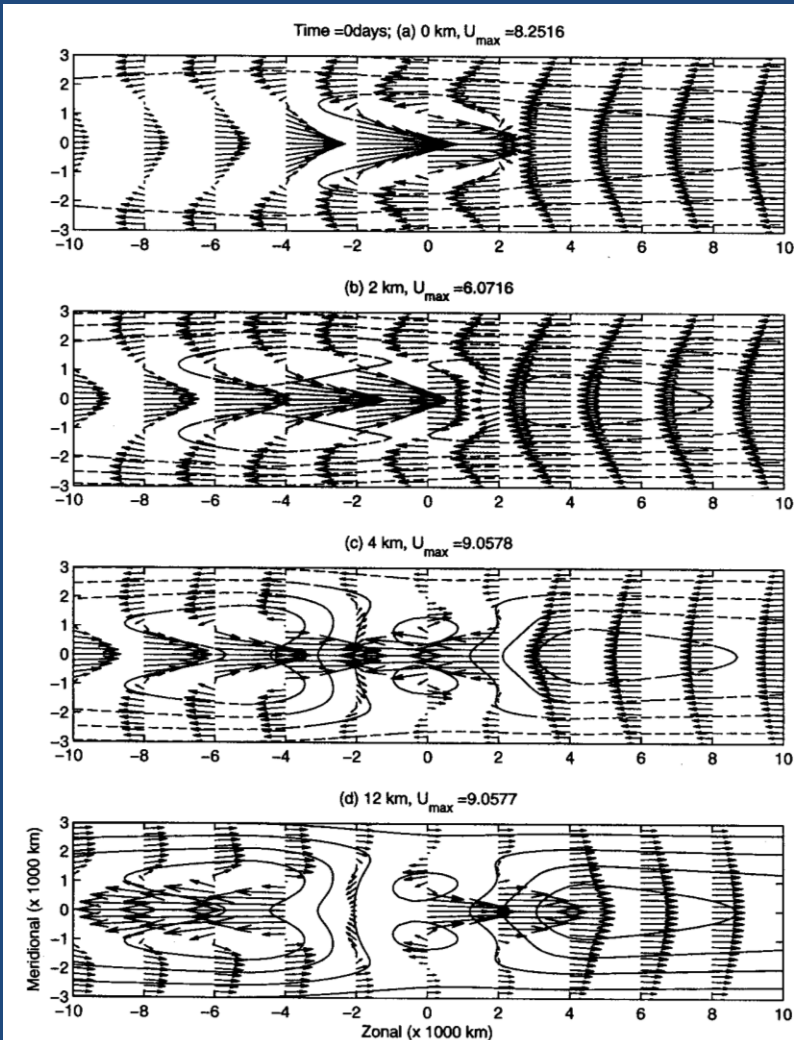

Vertical structure of the eastward propagating supercluster-like system

Dynamical model of organized convection interlocked with a Rossby-gyre circulation

Grabowski (2001)
Moncrieff (2004)

Upscale effects of MCS/superclusters on MJO

$$\bar{U}_t - y\bar{V} + \bar{P}_x = F^U - d_m \bar{U}$$

$$y\bar{U} + \bar{P}_y = 0$$

$$\bar{\theta}_t + \bar{W} = F^\theta - d_\theta + \bar{S}_\theta$$

$$\bar{P}_z = \bar{\theta}$$

$$\bar{U}_x + \bar{V}_y + \bar{W}_z = 0$$

$$F^U = -\overline{(v'u')_y} - \overline{(w'u')_z}$$

$$F^\theta = -\overline{(v'\theta')_y} - \overline{(w'\theta')_z}$$

Comment ...

- We have still to demonstrate the upscale cascade hypothesis for the MJO operates in full-physics prediction models
- Being addressed by the UK *Cascade* project and by NCAR Channel Model experiments

Improving convective parameterization

Representing MCS

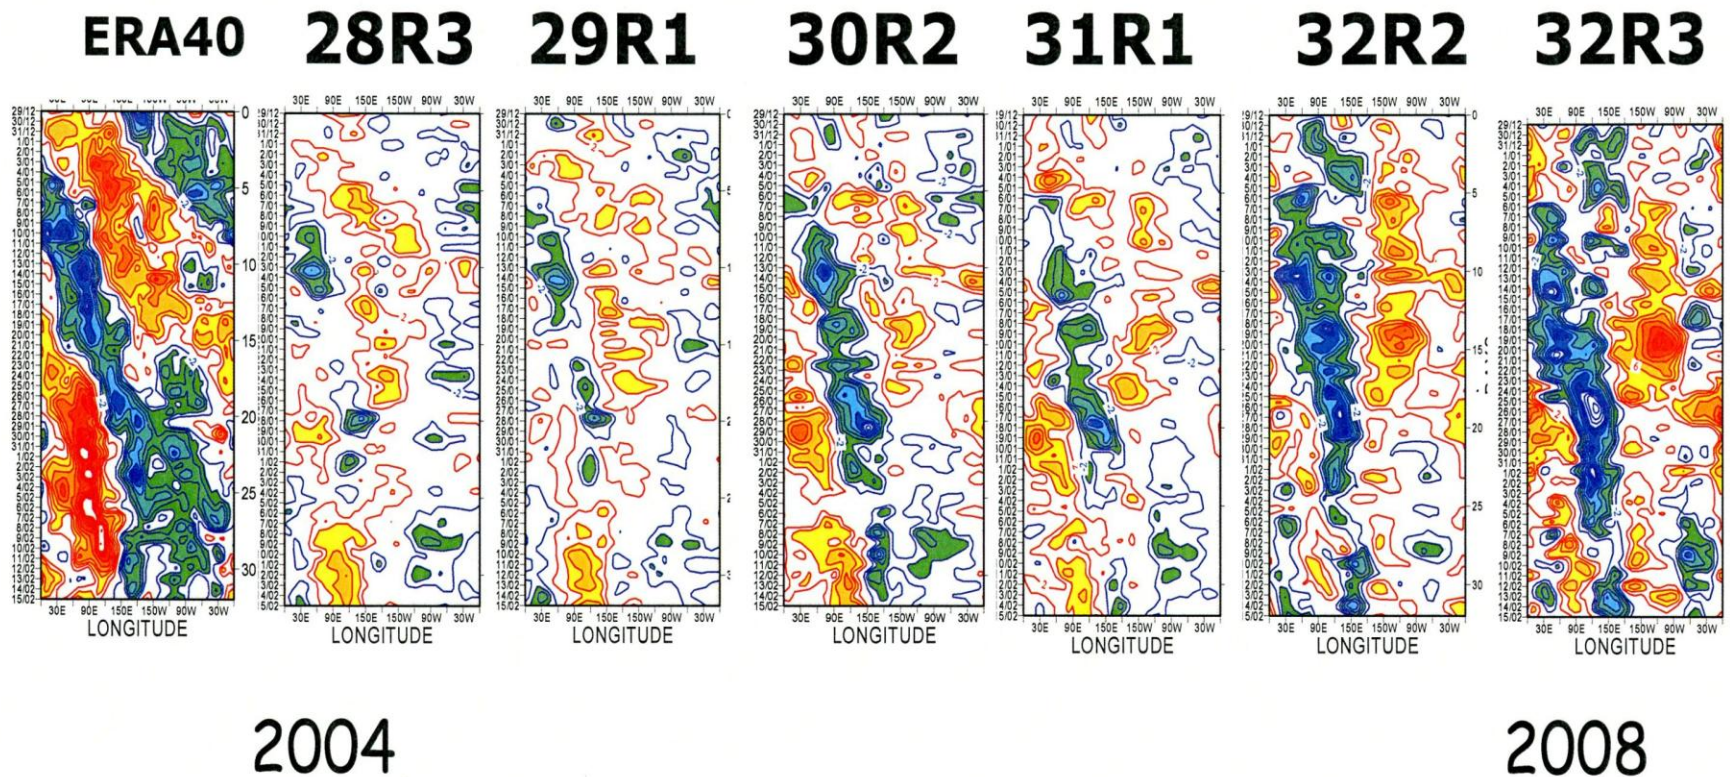

$$\Delta \square L$$

Climate models: traditional

$$\Delta \sim L$$

Weather models: hybrid

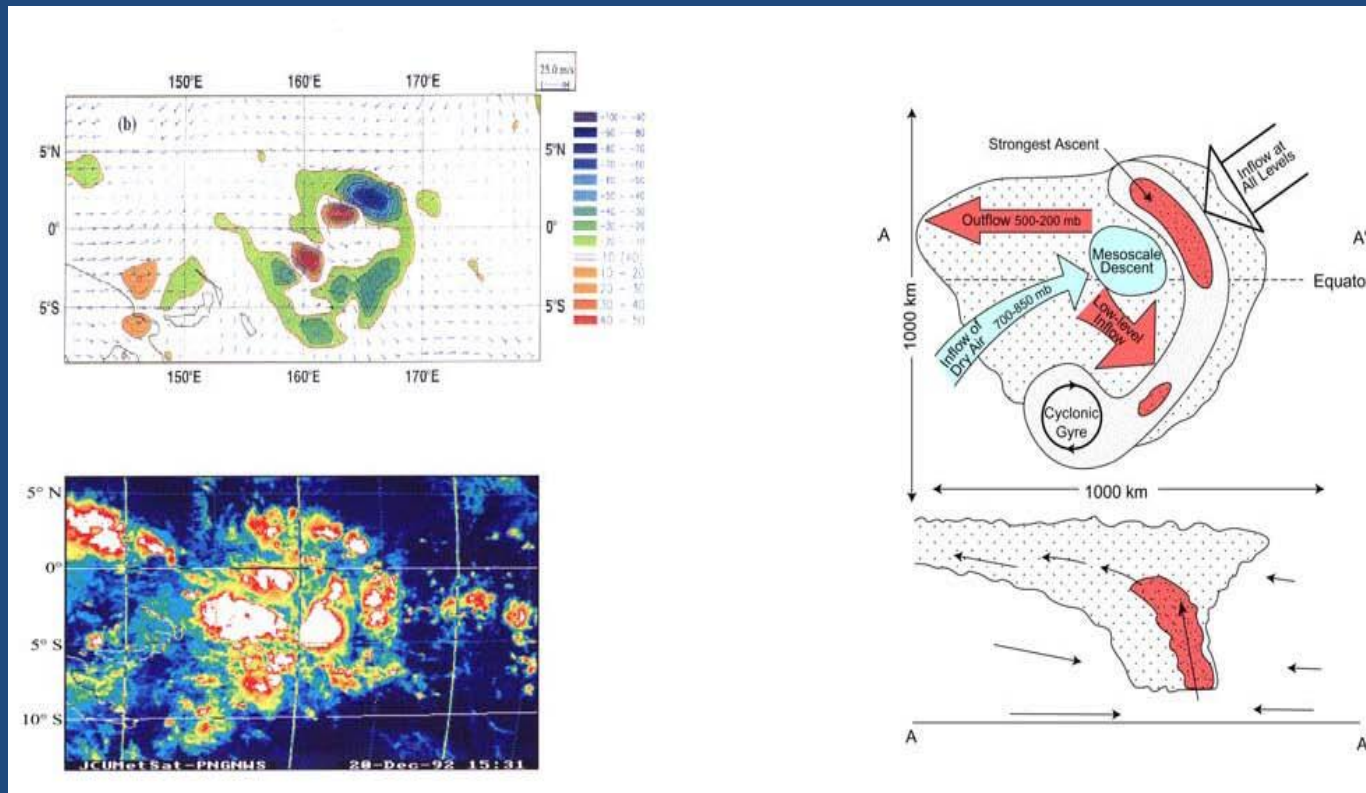

Improved MJO in ECMWF model

Do “grid-scale” circulations (under-resolved mesoscale organization) play a positive role? (Yes)

vs

Do convective parameterizations suppress organization? (Yes)

Carbone et al. (2002)

Parameterized & explicit precipitation

Resolution dependence

$\Delta = 3$ km

$\Delta = 10$ km

$\Delta = 30$ km

3-km & 10-km -- similar convective organization, amplitude too weak in 10 km
30-km – unrealistic

Global importance of MCS

Convective parameterizations do not represent organized dynamics

a)

Isolated convection, single grid volume

- Entraining plume (turbulent mixing)
- No environmental shear
- Local response
- Closed system
- Weak scale-interaction
- No gravity waves

b)

Organized convective system, many grid volumes

- Organized flow (mesoscale dynamics)
- Environmental shear
- Local and remote response
- Open system
- Strong scale-interaction
- Convectively-generated gravity waves

Conclusions

- **MCS-type convective organization occurs at different scales in explicit models**
- **Scale-gap of traditional convective parameterization been bridged, realistic mesoscale circulations in explicit models even 10-km-grid models**
- **Meso-convective organization (mesoscale dynamics) spontaneous in: global CRMs, superparameterized models (MMF), tropical channel models**
- **Relevant for seamless climate prediction, especially in terms of the distribution of precipitation and the diurnal cycle**
- **Meso-convective dynamics an important element of the “upscale cascade”**
- **Mesoscale circulations in 10-km-grid climate models occur as a hybrid parameterization, an improvement over traditional parameterization**
- **Challenge: representing meso-convective organization in traditional parameterizations**
